PROGRAMMING IN HASKELL

Chapter 7 - Higher-Order Functions

Introduction

A function is called <u>higher-order</u> if it takes a function as an argument or returns a function as a result.

twice ::
$$(a \rightarrow a) \rightarrow a \rightarrow a$$

twice $f x = f (f x)$

twice is higher-order because it takes a function as its first argument.

Why Are They Useful?

- Z Common programming idioms can be encoded as functions within the language itself.
- Z Domain specific languages can be defined as collections of higher-order functions.
- z Encapsulation using partial function application can be used to hide implementation details.
- Z Algebraic properties of higher-order functions can be used to reason about programs.

The Map Function

The higher-order library function called <u>map</u> applies a function to every element of a list.

map ::
$$(a \rightarrow b) \rightarrow [a] \rightarrow [b]$$

```
> map (+1) [1,3,5,7]
[2,4,6,8]
```

The map function can be defined in a particularly simple manner using a list comprehension:

map f
$$xs = [f x | x \leftarrow xs]$$

Alternatively, for the purposes of proofs, the map function can also be defined using recursion:

```
map f [] = []
map f (x:xs) = f x : map f xs
```

The Filter Function

The higher-order library function <u>filter</u> selects every element from a list that satisfies a predicate.

```
filter :: (a \rightarrow Bool) \rightarrow [a] \rightarrow [a]
```

```
> filter even [1..10]
[2,4,6,8,10]
```

Filter can be defined using a list comprehension:

```
filter p xs = [x \mid x \leftarrow xs, p x]
```

Alternatively, it can be defined using recursion:

The Foldr Function

A number of functions on lists can be defined using the following simple pattern of recursion:

```
f [] = v 
f (x:xs) = x \oplus f xs
```

f maps the empty list to some value v, and any non-empty list to some function ⊕ applied to its head and f of its tail.

```
sum [] = 0
sum (x:xs) = x + sum xs
```

```
product [] = 1
product (x:xs) = x * product xs
```

The higher-order library function <u>foldr</u> (fold right) encapsulates this simple pattern of recursion, with the function \oplus and the value v as arguments.

```
sum = foldr (+) 0
product = foldr (*) 1
or = foldr (||) False
and = foldr (&&) True
```

Foldr itself can be defined using recursion:

```
foldr :: (a \rightarrow b \rightarrow b) \rightarrow b \rightarrow [a] \rightarrow b
foldr f v [] = v
foldr f v (x:xs) = f x (foldr f v xs)
```

However, it is best to think of foldr <u>non-recursively</u>, as simultaneously replacing each (:) in a list by a given function, and [] by a given value.

```
sum [1,2,3]
foldr (+) 0 [1,2,3]
foldr (+) 0 (1:(2:(3:[])))
1+(2+(3+0))
6
                   Replace each (:)
                 by (+) and [] by 0.
```

```
product [1,2,3]
foldr (*) 1 [1,2,3]
foldr (*) 1 (1:(2:(3:[])))
1*(2*(3*1))
6
                   Replace each (:)
                 by (*) and [] by 1.
```

Other Foldr Examples

Even though foldr encapsulates a simple pattern of recursion, it can be used to define many more functions than might first be expected.

Recall the length function:

```
length :: [a] \rightarrow Int
length [] = 0
length (_:xs) = 1 + length xs
```

For example:

Hence, we have:

```
length [1,2,3]
length (1:(2:(3:[])))
1+(1+(1+0))
                     Replace each (:)
                      by \lambda_ n \rightarrow 1+n
                       and [] by 0.
```

length = foldr (λ _ n \rightarrow 1+n) 0

Now recall the reverse function:

```
reverse [] = []
reverse (x:xs) = reverse xs ++ [x]
```

For example:

```
reverse [1,2,3]
=
reverse (1:(2:(3:[])))
=
(([] ++ [3]) ++ [2]) ++ [1]
=
[3,2,1]
```

Replace each (:) by $\lambda x xs \rightarrow xs ++ [x]$ and [] by [].

Hence, we have:

reverse = foldr (
$$\lambda x \times xs \rightarrow xs ++ [x]$$
) []

Finally, we note that the append function (++) has a particularly compact definition using foldr:

$$(++ ys) = foldr (:) ys$$
Replace each (:) by (:) and [] by ys.

Why Is Foldr Useful?

- Z Some recursive functions on lists, such as sum, are <u>simpler</u> to define using foldr.
- z Properties of functions defined using foldr can be proved using algebraic properties of foldr,

z Advanced program <u>optimisations</u> can be simpler if foldr is used in place of explicit recursion.

Other Library Functions

The library function (.) returns the <u>composition</u> of two functions as a single function.

(.) ::
$$(b \rightarrow c) \rightarrow (a \rightarrow b) \rightarrow (a \rightarrow c)$$

f. $g = \lambda x \rightarrow f (g x)$

```
odd :: Int → Bool odd = not . even
```

The library function <u>all</u> decides if every element of a list satisfies a given predicate.

all :: (a
$$\rightarrow$$
 Bool) \rightarrow [a] \rightarrow Bool all p xs = and [p x | x \leftarrow xs]

```
> all even [2,4,6,8,10]
True
```

Dually, the library function <u>any</u> decides if at least one element of a list satisfies a predicate.

```
any :: (a \rightarrow Bool) \rightarrow [a] \rightarrow Bool
any p xs = or [p x | x \leftarrow xs]
```

```
> any (== ' ') "abc def"
True
```

The library function <u>takeWhile</u> selects elements from a list while a predicate holds of all the elements.

```
> takeWhile (/= ' ') "abc def"
"abc"
```

Dually, the function <u>dropWhile</u> removes elements while a predicate holds of all the elements.

```
> dropWhile (== ' ') " abc"
"abc"
```

The library function <u>curry</u> takes an uncurried function and constructs a curried version of this function.

```
curry :: ((a,b) -> c) -> (a -> b -> c)
curry f = \langle x y \rangle + f(x, y)
addUncurried :: (Int,Int) -> Int
addUncurried (x,y) = x+y
 addUncurried (1,2)
3
 curry addUncurried 1 2
3
> :t curry addUncurried :: Int -> Int -> Int
```

Dually, the library function <u>uncurry</u> takes a curried function and constructs an uncurried version of this function.

```
uncurry :: (a -> b -> c) -> ((a,b) -> c)
uncurry f = (x,y) \rightarrow f x y
addCurried :: Int -> Int -> Int
addCurried x y = x+y
 addCurried 1 2
3
 uncurry addCurried (1,2)
3
> :t uncurry addCurried :: (Int,Int) -> Int
```

Exercises

(1) What are higher-order functions that return functions as results better known as?

(2) Express the comprehension [f x | x ← xs, p x] using the functions map and filter.

(3) Redefine map f and filter p using foldr.
